

CLAIMS

1. An angular velocity sensor comprising:

a tuning fork vibrator having two arms and a base to
5 support the two arms together;

a drive unit formed on a main surface of each of the two
arms in order to drive each of the two arms in an X-axis
direction; and

a detection unit formed on a main surface of each of the
10 two arms in order to detect vibration of each of the two arms
in a Z-axis direction based on an angular velocity applied
around a Y-axis, wherein

the detection unit is made up of a bottom electrode formed
on the main surface of each of the two arms, a piezoelectric
15 film formed on the bottom electrode, and a top electrode formed
on the piezoelectric film;

the main surface having the detection unit thereon and
a tilted side surface adjacent to the main surface cross each
other at an acute angle; and

20 a center of at least the top electrode of the detection
unit is shifted from a center of the main surface to a side
opposite to the tilted side surface.

2. The angular velocity sensor of claim 1, wherein

25 the main surface of each of the two arms having the

detection unit thereon and the tilted side surface adjacent to the main surface cross each other at an acute angle; and

the center of at least the top electrode of the detection unit is shifted by a specific amount in accordance with a degree of tilt of the tilted side surface from the center of the main surface to the side opposite to the tilted side surface.

3. An angular velocity sensor comprising:

a tuning fork vibrator having two arms and a base to support the two arms together;

a drive unit formed on a main surface of each of the two arms driving each of the two arms in an X-axis direction; and

a detection unit formed on a main surface of each of the two arms in order to detect vibration of each of the two arms in a Z-axis direction based on an angular velocity applied around a Y-axis, wherein

the detection unit is made up of a bottom electrode formed on the main surface of each of the two arms, a piezoelectric film formed on the bottom electrode, and a top electrode formed on the piezoelectric film;

the main surface having the detection unit thereon and a tilted side surface adjacent to the main surface cross each other at an obtuse angle; and

a center of at least the top electrode of the detection unit is shifted from a center of the main surface to the tilted

side surface.

4. The angular velocity sensor of claim 3, wherein

the main surface of each of the two arms having the
5 detection unit thereon and the tilted side surface adjacent to
the main surface cross each other at an obtuse angle; and

the center of at least the top electrode of the detection
unit is shifted by a specific amount in accordance with a degree
of tilt of the tilted side surface from the center of the main
10 surface to the tilted side surface.

5. The angular velocity sensor of claim 1 or 3, wherein

the drive units are made up of bottom electrodes formed
on the main surface of each of the two arms across the center
15 of the main surface, piezoelectric films formed on the bottom
electrodes, and top electrodes formed on the piezoelectric
films in such a manner as to be away from each other across the
center of the main surface.

20 6. The angular velocity sensor of claim 1 or 3, wherein

the drive units are made up of bottom electrodes formed
away from each other across the center of the main surface of
each of the two arms, piezoelectric films respectively formed
on the bottom electrodes, and top electrodes respectively
25 formed on the piezoelectric films.

7. The angular velocity sensor of claim 1 or 3, wherein the tuning fork vibrator is formed by dry etching.

5 8. The angular velocity sensor of claim 1 or 3, wherein the tuning fork vibrator is made of a silicon-based material.

9. An angular velocity sensor comprising:

a tuning fork vibrator having two arms and a base to
10 support the two arms together;

a drive unit formed on a main surface of each of the two arms in order to drive each of the two arms in an X-axis direction; and

a detection unit formed on a main surface of each of the
15 two arms in order to detect vibration of each of the two arms in a Z-axis direction resulting from an angular velocity applied around a Y-axis, wherein

the drive unit is made up of a bottom electrode formed on the main surface, a piezoelectric film formed on the bottom
20 electrode, and a top electrode formed on the piezoelectric film;

the main surface having the drive unit thereon and a tilted side surface adjacent to the main surface cross each other at an acute angle; and

an amount of Y-axis deformation of a part of the drive
25 unit that is on a tilted side surface side of the center of the

main surface is smaller than an amount of Y-axis deformation of a part of the drive unit that is on a side opposite to the tilted side surface side of the center of the main surface when the two arms are driven in the X-axis direction.

5

10. The angular velocity sensor of claim 9, wherein

the drive units are made up of bottom electrodes formed on the main surface of each of the two arms across the center of the main surface, piezoelectric films formed on the bottom
10 electrodes, and top electrodes formed on the piezoelectric films in such a manner as to be away from each other across the center of the main surface.

11. The angular velocity sensor of claim 9, wherein

15 the drive units are made up of bottom electrodes formed away from each other across the center of the main surface of each of the two arms, piezoelectric films respectively formed on the bottom electrodes, and top electrodes respectively formed on the piezoelectric films.

20

12. The angular velocity sensor of claim 10 or 11, wherein

the main surface of each of the two arms having the drive units thereon and a tilted side surface adjacent to the main surface cross each other at an acute angle;

25

the top electrode that is formed on the tilted side surface

side of the center of the main surface is smaller in width in the X-axis direction than the top electrode that is formed on a side opposite to the tilted side surface side of the center of the main surface; and

5 both the top electrodes have an equal center position and an equal length in a Y-axis direction.

13. An angular velocity sensor comprising:

10 a tuning fork vibrator having two arms and a base to support the two arms together;

 a drive unit formed on a main surface of each of the two arms in order to drive each of the two arms in an X-axis direction; and

15 a detection unit formed on a main surface of each of the two arms in order to detect vibration of each of the two arms in a Z-axis direction resulting from an angular velocity applied around a Y-axis, wherein

 the drive unit is made up of a bottom electrode formed on the main surface, a piezoelectric film formed on the bottom electrode, and a top electrode formed on the piezoelectric film;
20 and

 in a case where the main surface having the drive unit thereon and a tilted side surface adjacent to the main surface cross each other at an obtuse angle, an amount of Y-axis
25 deformation of a part of the drive unit that is on a tilted side

surface side of the center of the main surface is made larger than an amount of Y-axis deformation of an other part of the drive unit that is on a side opposite to the tilted side surface side of the center of the main surface when the two arms are
5 driven in the X-axis direction.

14. The angular velocity sensor of claim 13, wherein

the drive units are made up of bottom electrodes formed on the main surface of each of the two arms across the center
10 of the main surface, piezoelectric films formed on the bottom electrodes, and top electrodes formed on the piezoelectric films in such a manner as to be away from each other across the center of the main surface.

15 15. The angular velocity sensor of claim 13, wherein

the drive units are made up of bottom electrodes formed away from each other across the center of the main surface of each of the two arms, piezoelectric films respectively formed on the bottom electrodes, and top electrodes respectively
20 formed on the piezoelectric films.

16. The angular velocity sensor of claim 14 or 15, wherein

when the main surface of each of the two arms having the drive units thereon and a tilted side surface adjacent to the
25 main surface cross each other at an obtuse angle, the top

electrode that is formed on the tilted side surface side of the center of the main surface is larger in width in the X-axis direction than the top electrode that is formed on a side opposite to the tilted side surface side of the center of the main surface, and both the top electrodes have an equal center position and an equal length in a Y-axis direction.

17. The angular velocity sensor of claim 9 or 13, wherein the tuning fork vibrator is formed by dry etching.

18. The angular velocity sensor of claim 9 or 13, wherein the tuning fork vibrator is made of a silicon-based material.

19. The angular velocity sensor of claim 9 or 13, wherein the detection unit formed on the main surface of each of the two arms is made up of a bottom electrode formed on the main surface of, a piezoelectric film formed on the bottom electrode, and a top electrode formed on the piezoelectric film.

20. A method for manufacturing an angular velocity sensor comprising: a tuning fork vibrator having two arms and a base to support the two arms together; a drive unit formed on one main surface of each of the two arms in order to drive each of the two arms in an X-axis direction; and a detection unit formed on the main surface of each of the two arms in order to detect

vibration of each of the two arms in a Z-axis direction resulting from an angular velocity applied around a Y-axis, the method comprising:

forming a bottom electrode on an XY surface of a substrate;

5 forming a piezoelectric film on the bottom electrode;

forming a top electrode on the piezoelectric film;

forming the drive unit and the detection unit from the bottom electrode, the piezoelectric film and the top electrode; and

10 forming the tuning fork vibrator by dry etching the substrate in such a manner that a Y-axis direction of the two arms coincides with a Y-axis direction of the substrate, wherein

as an incident angle of plasma used for the dry etching on a YZ surface of the substrate gets larger,

15 a center of at least the top electrode of the detection unit formed on the main surface is made to be shifted by a specified amount from a center of the main surface towards an X-axis edge of the substrate.
